Abstract

Aims: To compare the long-term outcomes of mechanical valves as opposed to bioprosthetic valves in order to inform valve selection.

Methods and results: From January 1996 to December 2010, 561 patients aged 60 to 75 years undergoing AVR for the first time were evaluated (mechanical valve: N=251; bioprosthetic valve: N=310). The primary outcome was all-cause death, and secondary outcomes were reoperation, bleeding events, thromboembolism, endocarditis and major adverse prosthesis-related events (MAPE). MAPE were the composite of reoperation, bleeding, thromboembolism and endocarditis. Long-term outcomes were compared with the use of propensity scores to adjust for selection bias. After risk adjustment, both groups of patients showed a similar risk of death at 10 years (hazard ratio [HR] 1.25, 95% confidence interval [CI]: 0.85-1.85, p=0.26), reoperation (HR 2.94, 95% CI: 0.79-11.11, p=0.11) and thromboembolism (HR 0.38, 95% CI: 0.10-1.40, p=0.15). Compared with the patients given mechanical valves, those who received bioprosthetic valves were at a higher risk of endocarditis (HR 7.65, 95% CI: 1.74-33.52, p=0.007), but were however at a lower risk of bleeding (HR 0.25, 95% CI: 0.12-0.52, p<0.0001) and MAPE (HR 0.61, 95% CI: 0.39-0.96, p<0.033).

Conclusions: Compared with mechanical AVR, bioprosthetic AVR showed a similar long-term survival rate and favourable MAPE event rate.

- TAVR: transcatheter aortic valve replacement

**Introduction**

The current American Heart Association guidelines recommend mechanical valves for aortic valve replacement (AVR) in patients younger than 60 years, and bioprosthetic valves in patients older than 70 years. Either a bioprosthetic or a mechanical valve is recommended between 60 and 70 years. This grey zone reflects the current trend towards increasing use of bioprostheses in progressively younger patients, and also the complexities and trade-offs of selecting an aortic valve prosthesis in older patients. Patients with mechanical valves require lifelong anticoagulation, and risk of bleeding events increases with advancing age. In contrast, risk of reoperation in patients with bioprosthetic valves increases with time and decreases with advancing age.

Two historic randomised clinical trials compared outcomes after valve replacement with first-generation bioprosthetic and mechanical valves. Although these trials are notable for their prospective, randomised design, their major limitations are that comparisons were made between first-generation valves, and most of the study population in these trials was under 60 years of age. Furthermore, recent innovation in transcatheter aortic valve replacement (TAVR) is applicable to replace deteriorated biological prostheses, which may affect the strategy in case of reoperation for octogenarians and their late survival. To address the limitations of the earlier randomised trials, a new randomised trial demonstrated the similar survival rate between bioprosthetic and mechanical valves but higher incidence of bleeding events in mechanical valves and more frequent reoperation in bioprosthetic valves. Recently, large registry data gave support to this with a similar result. However, it is not clear whether this finding is applicable to other populations, including an Asian population. Thus, we conducted a long-term observational study to compare outcomes of mechanical and bioprosthetic valve replacement for patients aged more than 60 years in an Asian population.

**Methods**

**STUDY DESIGN**

Patients who underwent valve surgery at our institution were prospectively registered using a standard case-reporting form. Case report forms, including patient demographics, clinical presentation, echocardiographic data, and procedural data were stored in an electronic database. Clinical follow-up data of study patients were prospectively collected via clinical visits or telephone, and entered into the database at one month and six months after operation, and subsequently on an annual basis. From January 1996 to December 2010, a total of 773 patients undergoing AVR with a mechanical or bioprosthetic valve were consecutively enrolled in the present study. The criteria for exclusion from the study were defined as patients undergoing urgent surgery, or non-coronary artery bypass graft cardiac surgical procedures, those with a prior history of any valve replacement and who had received AVR for infective endocarditis or (Figure 1A). All patients provided informed consent, and the study was approved by the institutional review board.

**CHOICE OF PROSTHESIS AND SURGICAL PROCEDURES**

The selection of a mechanical or a bioprosthetic valve was made following a detailed preoperative discussion among the surgeon, the patient, and family members. The pros and cons of mechanical or bioprosthetic valves were described, including the need for anticoagulation after mechanical valve replacement or the possible need for reoperation after bioprosthetic valve replacement. The decision on mechanical or bioprosthetic selection was left entirely to the individual patient and his/her carers. The operation was conducted in the standard manner. Briefly, all patients underwent AVR through a median sternotomy. A standard cannulation was performed in the routine fashion. After having clamped the aorta and arrested the heart with antegrade/retrograde cold blood, or cold crystalloid cardioplegia added to topical cooling, the ascending aorta was opened and the valve was replaced, either by a bioprosthetic or a mechanical valve fixed to the aortic annulus.

**ANTICOAGULATION**

During the postoperative period, anticoagulated patients initially received unfractionated heparin until the international normalised ratio (INR) was within therapeutic range. Patients with mechanical prostheses were anticoagulated with warfarin according to our protocol to a target of INR 2.5 (range, 2.0 to 3.0). In patients who underwent bioprosthetic valve replacement, warfarin anticoagulation was used at the discretion of the surgeon for a period of three months after the operation. Warfarin was subsequently discontinued if sinus rhythm was maintained and no other indication for anticoagulation was present. Non-anticoagulated patients with bioprosthetic valves were kept on 100 mg of aspirin daily unless contraindicated.

**OUTCOMES**

The primary endpoint was the rate of death from any cause over the duration of follow-up. Secondary endpoints were aortic valve reoperation, bleeding events, thromboembolism and endocarditis. Major adverse prosthesis-related events (MAPE) were the composite of reoperation, bleeding events, thromboembolism and endocarditis. These complications were defined according to the guidelines for reporting mortality and morbidity after cardiac valve intervention. Briefly, a bleeding event is any episode of major internal or external bleeding that causes death, hospitalisation, or
comes. Unadjusted hazard ratios and adjusted hazard ratios were
censoring was assumed to be independent of predictors and out-
the time of death if the outcome of interest had not occurred, and
Patients were censored at the time of their last follow-up visit or at

STATISTICAL ANALYSIS
Continuous variables are presented as the mean±standard devia-
tion, and they were compared using the Student’s t-test. Categorical
variables are presented as counts or percentages, and they were
compared using the chi-square test. A log-rank test was used to
compare mortality and event rates between mechanical and bio-
prosthetic valves. A nonparametric Kaplan-Meier estimate was
used to estimate the survival curve. To adjust for the difference
in baseline characteristics between mechanical and bioprosthetic
valves, the propensity score was estimated using the twang package
in the R version 3.0.1 based on age, gender, body surface area, dia-
betes mellitus, hypertension, smoking status, previous myocardial
infarction, previous stroke, New York Heart Association functional
state, atrial fibrillation, chronic renal failure, left ventricular ejection
fraction, and coronary artery bypass grafting. The propensity
score matching was performed by matching between mechanical
and bioprosthetic valve groups on the logit of the propensity score
using a calliper of 0.2 SD of the logit of the propensity score 10.
Patients were censored at the time of their last follow-up visit or at
the time of death if the outcome of interest had not occurred, and
censoring was assumed to be independent of predictors and out-
comes. Unadjusted hazard ratios and adjusted hazard ratios were
derived from a Cox proportional hazards model with propensity

Results
PATIENT CHARACTERISTICS
A total of 561 patients (mechanical valve, N=251; bioprosthetic
valve, N=310) were analysed in this study, and 531 patients
(95.4%) completed follow-up. Patient age was 67.5±4.5 years
(range, 60 to 75 years) at the time of surgery (Table 1). There were
319 (56.9%) male and 242 (43.1%) female patients. A total of 159
(28.3%) patients were in New York Heart Association (NYHA)
functional Class III or IV. The total follow-up for the entire cohort
was 3,167 patient-years, with a mean duration of 5.6 years (inter-
quartile range: 2.2 to 8.3 years; maximum 15.6 years). The dis-
tribution of mechanical and bioprosthetic valves was constant
across the age range (Figure 1B). Compared with patients who
received mechanical valves, those who received bioprosthetic
valves had lower body surface area and ejection fraction, but
a similar age and prevalence of most other comorbidities. It was
noted that patients with bioprosthetic valves were more likely to
undergo concomitant coronary artery bypass graft surgery (28.1%
versus 21.1%) but the difference did not reach statistical signifi-
cance. The dominant underlying lesion was either isolated aortic
stenosis (252 patients; 44.9%) or mixed aortic stenosis and regur-
gitation (182 patients; 32.4%). Intraoperative characteristics were
similar for patients with bioprosthetic versus mechanical valves,
with a similar mean time on cardiopulmonary bypass and aorta

cross clamp time (Table 2).

AF: atrial fibrillation; CABG: coronary artery bypass graft; MI: myocardial infarction; NYHA: New York Heart Association functional class
CLINICAL OUTCOMES

There were no differences in early outcomes between mechanical and bioprosthetic valves (Table 3). Four patients died after the index procedure in the mechanical group (1.6%), and eight patients died in the bioprosthetic group (2.6%, p=0.42).

In this registry, the 10-year cumulative mortality rate after AVR was 28.3% for patients who received mechanical valves and 31.6% for those who received bioprosthetic valves (unadjusted hazard ratio [HR] 1.30, 95% confidence interval [CI]: 0.91-1.86, p=0.15) (Figure 2A, Table 4). After risk adjustment, patients who received bioprosthetic valves experienced a similar long-term survival rate to those who received mechanical valves (adjusted HR 1.25, 95% CI: 0.85-1.85, p=0.26) (Figure 2B, Table 5).

The 10-year cumulative reoperation rates were 1.3% for patients who received mechanical valves and 5.8% for those who received bioprosthetic valves (Table 4). The incidence of aortic valve reoperation was higher among patients who received bioprosthetic valves than among those who received mechanical valves although the difference did not reach statistical significance (unadjusted HR 2.70, 95% CI: 0.73-10.00; p=0.14). The result from the propensity score-matched cohort was similar (adjusted HR 2.94, 95% CI: 0.79-11.11, p=0.11) (Figure 3A, Table 5).

The 10-year incidence of bleeding events was 24.5% for patients given mechanical valves and 6.9% for those given bioprosthetic valves as shown in (unadjusted HR 0.30, 95% CI: 0.16-0.54, p<0.0001) (Table 4). After risk adjustment, patients who received bioprosthetic valves had a lower risk of bleeding (adjusted HR 0.25, 95% CI: 0.12-0.52, p<0.0001) (Figure 3B). Among bleeding events, cerebral haemorrhage was lower in patients who received bioprosthetic valves (unadjusted HR 0.12, 95% CI: 0.01-0.97, p=0.046), but this statistically significant difference diminished after risk adjustment (adjusted HR 0.15, 95% CI: 0.02-1.22, p=0.08). Among bioprosthetic valves experienced a similar long-term survival rate to those who received mechanical valves (adjusted HR 1.25, 95% CI: 0.85-1.85, p=0.26) (Figure 2B, Table 5).

*p-value was estimated by log-rank test. MAPE: major adverse prosthesis-related events

51 patients who experienced bleeding events, 30 patients required hospitalisation (mechanical valve, n=22; bioprosthetic valve, n=8).

There was a significant difference in the cumulative incidence of subsequent hospitalisation between the two groups (14.4% vs. 4.5%, p=0.009). Overall in-hospital duration was 12.0±19.7 days (mechanical valve, 14.2±23.4 days; bioprosthetic valve, 7.1±5.2 days, p=0.35). Among those who experienced bleeding events, 26 patients received a transfusion (mechanical valve, n=21; bioprosthetic valve, n=5). There was a significant difference in the cumulative incidence of receiving a transfusion (14.3% vs. 2.3%, p<0.001). There were no differences between the two groups in terms of units of transfused red blood cells, (3.3±1.8 units vs. 4.3±2.1 units, p=0.47), nor with fresh frozen plasma (3.5±1.8 units vs. 4.0±2.7 units, p=0.67). In line with total bleeding events, patients given a mechanical valve had a higher risk of hospitalisation due to a bleeding event (unadjusted HR 0.38, 95% CI: 0.18-0.81, p=0.012), as well as receiving a transfusion (unadjusted HR 0.23, 95% CI: 0.09-0.55, p=0.001).

The 10-year incidence of thromboembolism was similar between patients receiving mechanical and bioprosthetic valves (5.1% versus 6.5%; unadjusted HR, 1.03; 95% CI, 0.45 to 2.38; p=0.94) (Table 4). There were no significant differences in the thromboembolism rate after risk adjustment (unadjusted HR 0.38, 95% CI: 0.10-1.40, p=0.15) (Figure 3C). In contrast, patients with bioprosthetic valves showed a trend towards more frequent endocarditis compared to those with mechanical valves (unadjusted HR 4.14, 95% CI: 0.91-18.87, p=0.067). This trend became evident after risk adjustment (adjusted HR 7.65, 95% CI: 1.74-33.52, p=0.007) (Figure 3D).

By 12 years, MAPE had occurred in 29.6% of patients with mechanical valves and in 16.8% of patients with bioprosthetic valves (unadjusted HR 0.61, 95% CI: 0.40-0.92, p=0.017) (Figure 3E). After risk adjustment, patients who received bioprosthetic valves had a lower risk of MAPE (adjusted HR 0.61, 95% CI: 0.39-0.96, p=0.033) (Figure 3F).

SUBGROUP ANALYSIS OF LONG-TERM MORTALITY

Long-term mortality in the mechanical and bioprosthetic groups was compared by patient subgroup (Figure 4). The risk of mortality
varied across patient characteristics. In general, the long-term mortality of patients who received bioprosthetic valves was similar to that of those who received mechanical valves. However, the long-term mortality of patients treated with bioprosthetic valves was higher in female and NYHA Class III/IV subgroups compared to those with mechanical valves.

MAPE: major adverse prosthesis-related events

Discussion

This observational study of 561 patients between 60 and 75 years of age who underwent AVR with mechanical valves and bioprosthetic valves demonstrates that: 1) overall mortality was similar for patients with mechanical and bioprosthetic valves; 2) bleeding events were more common in patients with mechanical valves but endocarditis was more frequent in those with bioprosthetic valves; 3) reoperation tended to occur more frequently in patients with bioprosthetic valves; and 4) overall composite events were more frequent in patients given mechanical valves.

In the Veterans Administration Study, patients who underwent AVR with mechanical valves had a significantly higher 15-year survival rate than those with bioprosthetic valves. Brown et al, in a one-to-one study, matched patients aged 50 to 70 years undergoing AVR and found a 10-year survival of 68% in the mechanical valve group and 50% in the bioprosthetic valve group. However, other studies demonstrated similar long-term survival. In the Edinburgh Heart Valve Trial, at 12 years there was a survival advantage in the mechanical valve group compared with the bioprosthetic valve group, but this advantage disappeared at 20 years. Brennan et al compared outcomes of the Medicare-linked cohort study and found patients given a bioprosthesis had a similar adjusted risk for death. Lung and Bland in a meta-analysis with regression analyses did not find significant differences in the survival rate between mechanical and bioprosthetic valves after correcting for age. Our data was consistent with these previous studies. In the present study, 10-year mortality was 35.7% in patients with mechanical valves and 38.0% in those with bioprosthetic valves (p=0.15). Adjusted outcomes showed no difference in 10-year mortality between the two groups.

Previously, the advantages and disadvantages of mechanical or bioprosthetic valves have been well documented. The advantageous durability of mechanical valves is offset by the risk of thromboembolism and the need for long-term anticoagulation and its associated risk of bleeding. In contrast, bioprosthetic valves do not require long-term anticoagulation yet carry the risk of structural failure and reoperation. In our study, bleeding events were more common in patients with mechanical valves, but endocarditis was more frequent in those with bioprosthetic valves. Reoperation tended to occur more frequently in patients with bioprosthetic valves; however, thromboembolism did not show a difference between the two groups. Due to the large number of bleeding events, overall MAPE rates were higher for patients with mechanical valves. Although treating reoperation and bleeding events equally is controversial,

![Figure 4. Comparison of long-term mortality in mechanical and bioprosthetic groups by patient subgroup. AF: atrial fibrillation; EF: ejection fraction; HR: hazard ratio](image-url)
promising less invasive treatment for degenerated bioprostheses (“valve-in-valve” TAVR) would allow us to consider the composite MAPE as non-negligible. In addition, the superior durability of current bioprostheses favours the selection of a bioprosthetic valve.

Bleeding, where the event rate ranges from 13.7% at 10 years to 24.4% at 15 years, is the Achilles heel of the mechanical valve. In addition to the risk of bleeding, warfarin requires restrictions on food, alcohol and drugs, and lifelong coagulation monitoring. To overcome this complication of mechanical valves, new oral anticoagulation was applied in a randomised trial, but failed because of an excess of thromboembolic and bleeding events. Thus, a quality of life study needs to be instigated on the choice of prosthesis.

There is a paucity of Asian data on the long-term outcomes of aortic valve replacement with mechanical and bioprosthetic valves. The risk of bleeding and thromboembolism has been shown to be different according to race, as was the chance of bioprosthetic valve degeneration. Therefore, our data will provide important information for the selection of prosthetic valves for AVR in an Asian population.

The physicians involved in the decision-making process should be very aware of patient outcomes with the use of different prostheses. An increasing risk of major adverse effects and lifestyle alteration, i.e., lifelong anticoagulation with warfarin after mechanical valve replacement, improved durability of new technologies but still relatively higher risk of reoperation after bioprosthetic valve replacement, the potential option of minimally invasive procedures in case of reoperation and, finally, the individual patient’s preference, should be fully discussed with the patient.

Study limitations

Our study has several important limitations. First, it was a single-centre observational study and may be subject to selection bias and confounding by unmeasured severity of illness which may be correlated with the use of different valves. Second, the number of patients and follow-up time duration were limited, and it is likely that reoperation after bioprosthetic valve replacement will increase. Finally, we could not reliably ascertain other important endpoints, such as cardiovascular symptoms, functional status or decrements in quality of life associated with the use of anticoagulation therapy for mechanical valves and the monitoring of anticoagulant dosages. Despite these limitations, the current analysis demonstrates clear findings in agreement with reported data, and provides important information to guide valve type selection for older patients in current daily practice.

Conclusions

The following observations should be made: 1) overall mortality was similar for patients with mechanical and bioprosthetic valves; 2) bleeding events were more common in patients with mechanical valves but endocarditis was more frequent in those with bioprosthetic valves; 3) overall composite events were more frequent in patients given mechanical valves.

Impact on daily practice

The trend in current practice seems to be more use of bioprosthetic AVR with the possibility to use TAVR if prosthetic valve stenosis or regurgitation occurs. Although this strategy needs further investigation, our study provides important information about the choice of prosthesis in older patients.

Funding

This study was supported by a grant from the CardioVascular Research Foundation, Seoul, Republic of Korea.

Conflict of interest statement

The authors have no conflicts of interest to declare.
